

Voice of the customer

Multiple research sources show us that terminology - the words, labels, and names used in the HubSpot product interface - is a persistent, structural UX problem.

The evidence comes from four sources:

- CSAT and pNPS survey analysis
- Support call transcripts
- Internal UX research
- Synthesis of evidence gathered for
 - ☰ [2026] Central Content Design strategy ,
 - ☰ Terminology: 2026 Content Design Vision , and other recent content design resources

Each source was gathered and assessed independently. Together, they describe the same problem from different angles.

What customers say in surveys

Over a 12-month period, we identified **37 confirmed terminology complaints** in CSAT and pNPS survey response, drawn from a keyword-filtered export of 108 responses and manually reviewed to exclude false positives.

All five themes - terminology confusion, inconsistent naming conventions, unclear wording, frustrating renames, and misleading labels - appear across multiple months and product areas, with no month recording zero complaints. The average CSAT score for these complaints is **2.6 out of 5**, and more than a third scored 1 or 2.

Customers describe the problem in strikingly direct terms. One wrote that HubSpot's *["terminology and labels are often in conflict between areas."](#)* Another said *["wording varies heavily."](#)* A third said *["everything is mislabelled — it feels like this was not built with humans in mind."](#)*

The even spread across five themes matters. This is not one team's naming problem or one badly chosen label. It is a product-wide pattern affecting naming, labelling, wording, and how we communicate change.

What happens when terminology goes wrong

Support call analysis surfaces cases where a name — not a missing feature or a broken workflow — was the direct cause of a customer problem.

When "Lists" was renamed to "Segments," multiple customers called support because they could no longer find their existing lists. One spent a full week confused. One pNPS detractor wrote: *"Renaming of lists to segments had no upside, only downside. I spent a week searching and being confused in my daily work, for no gain."*

In another case, a button labelled "Complete Purchase" caused a customer to delay a renewal out of fear of being charged immediately. Inconsistent field names — "Phone Number" in one place, "Tell" in another — forced a team into manual workarounds. Two near-identical property names — "Country/Region" and "Country/Region Code" — caused data entry errors that required manual cleanup.

These are cases where the name of something caused a customer to do the wrong thing, avoid doing the right thing, or call support for help with something they should have been able to do on their own. Support ticket data shows approximately **270 terminology-related tickets per month** over six months, with no downward trend.

What research tells us

Internal UX research consistently identifies terminology as a barrier to adoption and confidence. In a Breeze AI Agent Builder study, **35% of users reported feeling "not very confident"** about setting up an agent on their own, and the research directly attributes that low confidence to confusing terms like "Trigger" and "Knowledge." A separate agents content study concluded that *"terminology is the biggest determinant of user confidence."*

Synthesis of internal research and discussion surfaces cross-cutting patterns that go beyond individual terms. The same concept often has multiple names across the product: "Files," "Documents," and "Attachments" all refer to things customers think of as the same object, but each works differently in different contexts. One customer wrote: *"Very difficult to tell the difference between when I need a file vs. a document."* Similarly, "Landing pages" and "Website pages" create an artificial split that confuses customers who see the same function: *"I don't understand why new pages I create are sometimes created as landing pages vs. web pages."*

Scope words like "global," "default," and "corporate vs personal" fail to explain what they affect, leading to uncertainty and fear of editing. Implementation jargon — "modules," "wrappers," "sections" — leaks into the customer-facing UI, creating friction for people performing basic tasks. And object names hide

functional requirements that customers only discover when something goes wrong: *"Isn't clear that CTAs need to be HubSpot CTAs."*

What this evidence adds up to

Four independent evidence sources — survey data, support interactions, UX research, and internal synthesis — all converge on the same conclusion. Terminology is a measurable, persistent, product-wide UX problem that affects customer confidence, increases support load, and does not improve on its own.

The full evidence, methodology, and source data for each analysis is documented in the tabs that follow.
